Numerical simulation of laser propagation in MATLAB has become an essential tool for researchers and engineers working in optics, photonics, and laser engineering. Accurate modeling of how laser beams propagate through various media enables better design, optimization, and understanding of laser systems. MATLAB, with its powerful computational capabilities and extensive library support, offers an ideal platform for simulating complex laser behaviors efficiently. In this article, we will explore the fundamental concepts behind laser propagation, discuss common numerical methods employed in MATLAB, and provide practical guidance on implementing these simulations.

Understanding Laser Propagation

Nature of Laser Beams

Laser beams are characterized by their coherence, monochromaticity, and high intensity. The most common laser mode for propagation studies is the Gaussian beam, which describes how the beam's intensity and phase evolve as it travels through space and media. Understanding the fundamental properties of laser beams provides the foundation for effective numerical simulation.

Wave Equation and Propagation Principles

The propagation of laser light can be described mathematically by the wave equation, derived from Maxwell's equations. For many practical scenarios, especially where the beam is paraxial (i.e., divergence angles are small), the paraxial approximation simplifies the wave equation to a form that is easier to solve numerically.

Numerical Methods for Laser Propagation in MATLAB

Beam Propagation Method (BPM)

The Beam Propagation Method is one of the most widely used techniques for simulating laser beam evolution, particularly in waveguides and optical fibers. It involves solving the paraxial wave equation iteratively as the beam propagates through a medium.

- **Split-Step Fourier Method:** Divides the propagation into linear and nonlinear steps, alternating

between applying diffraction in the Fourier domain and phase changes in the spatial domain.

- **Finite Difference Time Domain (FDTD):** Solves Maxwell's equations directly in the time or frequency domain, suitable for complex media and ultrashort pulses.

Fresnel and Fraunhofer Diffraction Integrals

These integrals provide analytical solutions for certain propagation scenarios, such as free-space propagation over specific distances. Numerical implementation allows for modeling of diffraction effects and beam shaping.

Implementing Laser Propagation Simulation in MATLAB

Setting Up the Simulation Parameters

Before starting the numerical simulation, define the key parameters:

- **Wavelength (λ):** Typically in the visible or infrared range.
- **Initial Beam Profile:** Usually a Gaussian profile characterized by waist size w_0 .
- **Propagation Distance:** Total distance over which the beam is simulated.
- **Spatial Grid:** Discretization of the transverse plane with appropriate resolution.

Modeling Gaussian Beam Propagation

A practical starting point is simulating a Gaussian beam propagating in free space, which involves calculating the beam's waist evolution and intensity profile at different points.

Sample MATLAB code snippet:

```
%% matlab

% Define parameters

lambda = 1064e-9; % wavelength in meters

w0 = 1e-3; % initial waist size in meters

z_max = 0.1; % maximum propagation distance in meters

dz = 1e-4; % step size in meters
```

```
z = 0:dz:z_max;

% Spatial grid

x = linspace(-5w0, 5w0, 1024);

dx = x(2) - x(1);

[X, Y] = meshgrid(x, x);

% Initial beam profile

U0 = exp(- (X.^2 + Y.^2) / w0^2);

% Initialize field

U = U0;

% Loop over propagation steps

for ii = 1:length(z)

% Apply Fresnel diffraction integral or split-step method

U = propagateGaussian(U, dx, lambda, dz);

% Optional: store or visualize the field at each step

end

'''
```

(Note: The function `propagateGaussian` would implement the split-step Fourier method or Fresnel integral.)

Using the Split-Step Fourier Method

This method involves transforming the field into the frequency domain, applying phase shifts that account for diffraction, and transforming back to the spatial domain iteratively.

Key steps:

- Compute the Fourier transform of the field.
- Multiply by the transfer function $H(f_x, f_y) = \exp(-i \pi \lambda z (f_x^2 + f_y^2))$.
- Perform the inverse Fourier transform to obtain the propagated field.

MATLAB implementation outline:

```
```matlab
```

```
function U_out = propagateSplitStep(U_in, dx, lambda, dz)
```

```
[Nx, Ny] = size(U_in);
```

```
k = 2 pi / lambda;
```

```
% Spatial frequency coordinates
```

```
fx = (-Nx/2:Nx/2-1)/(Nx*dx);
```

```
fy = (-Ny/2:Ny/2-1)/(Ny*dx);
```

```
[FX, FY] = meshgrid(fx, fy);
```

```
% Transfer function
```

```
H = exp(-1i (pi lambda dz) (FX.^2 + FY.^2));
```

```

```

```
